

Operating-depth evidence export specification

Document ID: SH-AUDIT-OPERATIONS-001

Version: 1.0.0

As of: September 9, 2026

State: SYNTHETIC RELEASE CONTRACT

Owner: Finance release owner / business records stewards

Package and identities

business-operations-v1.0.0 is a separately versioned successor. Its ZIP includes enterprise books, seven unit CSV/SQLite packages, source/financial bridges, operating histories, executed client handovers, control exercises and a reviewed workbook. Every release records the clean source revision, model input fingerprint, source-file hashes, legacy-generation identity and explicit synthetic/calibration period role.

The seven package keys are foundry-field, atlas-meridian, advisory, willow, project-cradle, pale-sun and american-resource-utility. Corporate and shared Treasury/control populations remain available in the parent distribution. Original physical measurement units are retained separately from reporting-unit keys.

Fail-closed population contract

Reviewed source JSON declares every approved table and column, allowed scope values and unit/entity routing combination. Normal builds fail on new columns/tables, missing required scope, unexpected fact states or invalid reporting relationships. Only development mode can propose changes; proposed rules cannot publish a release.

SQLite exports contain reporting tables only. Integrity, exact table/column lists, source row order and every serialized cell are verified. Seven unit packages are explicit subsets of the validated parent population. CSV text is neutralized where it could be interpreted as an untrusted spreadsheet formula; numeric values remain usable. Source hashes and financial records retain provenance and timing.

Client and authority boundary

Client handovers are a separate allowlisted surface: generated workflow, executable tests, runbook, agreed scope, dependency/rights evidence, manifest and test results. The verifier rejects missing or extra files, modified bytes, wrong client/matter identity, missing proof and failed execution. This does not grant access to employee Pinakes, Collection sources, other clients or private evaluation material.

Synthetic export clearance is not production IAM. Source-owner authorization, tenant/client purpose, retention, legal holds and real deployment controls remain governed by their existing decision records and unresolved implementation issues.

Workbook and complete-artifact acceptance

The controlled six-sheet workbook presents regenerated financial source data, cash-obligation and ARR bridges, control outcomes and forecast attribution. The report-year selector recalculates its summary. All source cells, exact summary formula ranges, cached results and reconciliation formulas are independently checked against regenerated data. A stale input identity or changed workbook digest fails. No external links, macros or formula errors are accepted.

After the final workbook, client packages and reports are present, the complete output is scanned for credential markers, workstation paths, PII-shaped values, private evaluation field names, CSV injection, embedded objects and

external links. This technical check complements the strict population contract; it does not prove production authorization or control effectiveness.

Every file, including nested manifests and checksum files, is covered by a parent manifest and SHA-256 list. Sorted archive paths, fixed timestamps and normalized modes support byte reproduction from the same clean revision. CI rebuilds twice, compares the ZIP digest and publishes only the exact checked main-run artifact. Existing release tags and assets must never be replaced with different bytes.

Control FAIL/NOT_RUN outcomes, unpaid requests, infeasible schedules and unapproved operating authority stay visible. Passing software integrity is not an assertion that these business conditions are resolved.

Implementation: [operating successor](#). Financial boundary: [successor design](#).
