

Company edition inspection and reproduction

Document ID: SH-COMPANY-INSPECTION-2026-09-15

Version: 1.0.0 Prepared September 15, 2026 UTC. Execution/provenance instructions updated September 22, 2026 UTC. The completed period and September event cutoff below remain unchanged; new evidence is not backdated to this guide's original preparation date. This guide defines the package route. The [register](#) and final release receipt determine accepted scope; this working guide is not a delivery receipt.

Begin with the edition

Read `CONTRACT.json` and `MANIFEST.json` before querying data. They identify the exact source commit, component populations, known-on boundary, limitations and allowed joins. A repository snapshot contains historical and proposed documents as well as controlling records. Inclusion does not erase their original states. The three package components are the tracked public source graph, the composed financial/calibration/forecast package, and completed-period company records. Inventoried historical ZIPs are excluded from redistribution; their original locations, flags and hashes remain in the retained delivery indexes.

The packaging cutoff is August 31, 2026, with a separate event ledger through September 14 America/Los_Angeles. Financial source periods and forecast scenarios retain their own labels. Later-authored evidence is not available in an earlier known-on view: use the later of original evidence availability and the edition's publication/availability boundary. Actual import time is separate again.

Materiality follows represented activity. Every legal/consolidated balance and each of the seven business-line revenue/cost populations is reconciled; all declared employee, contract, invoice and obligation populations are included. Selected physical record chains state their surrounding populations and exclusions. They do not claim a daily warehouse, dispatch or mine simulator. A failed control is an inspectable outcome; an unresolved material source gap blocks the claim it affects. No universal monetary threshold or professional audit opinion is implied.

Five reading routes

Inspector	Forward trace	Reverse/reperformance
Financial/ tax	Owner directions → accepted adjustments/tax history → legal journals → eliminations → statements → exports	<code>enterprise.closeout.reperform</code> , standalone CSV/SQLite inspection, historical/current tax and asset schedules
IT	Effective workforce → access and qualifications → control evidence/review → revocation/restore	Completed-period validators, reference authorization negatives, pinned CompanyStore import/backup/restore receipt
Relevant regulator	Entity/site/activity → primary provision/version → fictional facts → expected occurrence → performance/report/exception	Current applicability, fourteen rail cases, fourteen permit condition populations, shipment qualification and visible failures
Investor	Ownership/rights and financing status → revenue/aging → margins/commitments/debt → cash and sovereignty	Treasury thirteen-week assumptions, member-source IDs, investment-purpose bridges, unpaid obligations and downside
Agentic evaluator	Contract/schema/population definitions → exact public originals → existing	Independent import, stable-ID joins, as-of/known-on filtering and scoped access negatives

CSV/SQLite tables

Company outputs are public synthetic evidence. Candidate work, private scenario truth, grading rules/results and NAILEX proprietary implementation remain outside this package under maintainer rules. Neither tests nor public manifests disclose private grading payloads.

Current accounting and ownership sources

The [accounting-basis successor](#) defines the synthetic management accrual presentation and exact correction scope. Legal books, financial consolidation and tax filing groups have separate boundaries. The edition makes no US GAAP or audit-opinion claim. Use the final release receipt to identify the implemented tax provision, payment states and numerical effects.

The [adopted directions](#) resolve corporate taxation from formation and the exact five-holder register. The [capital source](#) and [founder reconstruction](#) distinguish historical subscriptions, admission value, retained earnings and subsequent member cash. The \$183 million subscription history is not additional current cash. Funding requests preserve the established participation shares and issue no new units. The [investor route](#) joins those records to the same edition's financial results and funding limits.

The register's residuals identify specific rights and capability limits, evidence reviewed, impact, alternatives and next owner. Accepted packaging cannot establish an unknown covenant, side-letter disposition, lien release or unexercised runtime surface. Selected mine examinations and rail-event reporting remain distinct from complete monthly mine and railway compliance populations.

Financial and completed-period joins

The financial component also contains `capital_register.json`, six `capital_*.csv` schedules and the `statutory_*.json/CSV` workpapers beside the existing exports. These are supplemental company workpapers, not additional rows to add to the ledger or copies implicitly included in every unit's SQLite database. Join funding by `scenario`, `source_id` and `event_id`, and holders by `holder_id`; preserve the source-to-cash rounding bridge. Join tax by `scenario`, `taxpayer`, `jurisdiction` and `year`. Filing/settlement states and interentity payer roles remain distinct from financial consolidation. The manifest inventories these exact supplemental bytes.

The finance export directory is `content/enterprise/generated/company-closeout-v1/exports`. Its `export_schema.json` defines the existing table columns. `enterprise.sqlite3` contains `company/legal/consolidated` populations; seven unit extracts are filtered representations. Never add unit extracts to the enterprise tables or add legal statements to consolidated statements. Journal natural identity is `scenario`, `journal_id`, `line_no`; source IDs link adjustments and native evidence.

The completed-period directory is `content/enterprise/generated/completed-period-2026-08`. Its `records.json`, CSVs, manifest and lane receipt preserve people, positions, payroll, contracts, delivery, invoices, settlements, inventory/asset balances and September changes. Person IDs join payroll/access/qualification records; position count is not headcount. Current invoice IDs join contract, delivery and authority IDs. Current revenue and payroll are decompositions of existing source expenses/revenue, not additional journals to post on top of the finance package. Read the explicit source bridges.

Example read-only queries against the financial SQLite export:

```
SELECT scenario, entity, year, net_income_usd, ending_cash_usd
FROM annual_statements
WHERE entity = 'CONSOLIDATED'
ORDER BY scenario, CAST(year AS INTEGER);
```

```
SELECT scenario, source_id, entity, year, month, account, signed_usd
FROM enterprise_journal
WHERE source_id LIKE 'CO-%' OR source_id LIKE '%FF003%'
```

```
ORDER BY scenario, CAST(year AS INTEGER), CAST(month AS INTEGER), journal_id, line_no;
```

Dates and monetary values are represented explicitly in the existing schema; use decimal arithmetic for reconciliations rather than floating-point rounding. CSV spreadsheet-injection escaping is intentional and independently checked against the original SQLite values. No server pagination, hidden filters or retention window truncates the distributable CSV/SQLite files. Source-specific population and availability filters still apply.

Reproduce from the pinned source

Controlled publications use `python -m tools.company_closeout.publications`, the dated document-population successor to `tools/documents/build_controlled_publications.py`. It reuses that exact approved renderer, style and source artwork. The predecessor file is itself pinned by historical finance evidence and retains its original bytes. When running the maintainer's predecessor command, run the successor afterward, then `python tools/documents/build_institutional_catalog.py`; this restores the complete current publication population before catalog verification.

Use a real Git checkout of `MANIFEST.json`'s `source_commit`, then install the supported dependency environment. `uv.lock` and the repository requirement files remain source-pinned. Generated directories are temporary outputs, not controlling canon. Build from a clean checkout for a release; development outputs retain a dirty-source flag and cannot become an accepted package.

```
uv sync --frozen --all-extras
uv run python -m enterprise.closeout.build
uv run python -m enterprise.operations.completed_period
uv run python -m enterprise.operations.completed_period --check
uv run python -m enterprise.operations.september_custody
uv run python -m enterprise.operations.september_custody --check
uv run python -m enterprise.closeout.reperform enterprise/generated/company-closeout-v1
uv run python -m enterprise.operations.reperform_closeout --output var/company-closeout/company-
reperformance.json
uv run python -m tools.company_closeout.independent_import enterprise/generated/company-closeout-v1/exports
uv run python -m enterprise.ccf.company_closeout.instruments
uv run python -m enterprise.ccf.company_closeout.current_applicability --reperform-revenue
uv run python -m enterprise.ccf.company_closeout.rail_reporting
uv run python -m enterprise.ccf.company_closeout.shipment
uv run python -m enterprise.ccf.company_closeout.admin_completion
uv run python -m enterprise.ccf.company_closeout.restore_rehearsal
```

The composite reperformance command requires the August, September and finance outputs to identify the same clean source commit. It independently joins current invoices, legal balances, asset carrying values, payroll legal-employer expense, selected debt payments and September freight to the retained source journals. The separate `September records.json` is included in the completed-company-records component; it is not omitted merely because its native generator uses another directory.

The release builder uses `tools.company_closeout.compose` to pin the exact generated and tracked populations. Supply the release receipt's version and availability timestamp and a new contract filename. `--accepted` requires `--acceptance-pr` and `--adoption-path`: the builder verifies actual merged PR evidence through the repository API and requires the exact merge commit as the clean source revision. The scoped adoption source pins accepted implementation sources and explicitly preserves pending framework reviews, draft rights, failures and future duties. The public source archive retains mixed source states; acceptance never labels every included historical or proposed document controlling canon.

`tools.company_closeout.edition` builds a new immutable directory and deterministic ZIP. It refuses stale hashes, a mismatched source revision, omitted/extra members, symlinks, private components and contradictory acceptance metadata. It rechecks merge evidence when building an accepted package; offline verification checks the retained receipt and packaged adoption scope. The receipt identifies its actual API observation date. Offline hashes

alone do not independently prove a remote merge or professional acceptance. Do not replace an existing archive under the same version.

```
uv run python -m tools.company_closeout.edition --output /new/edition --contract /new/CONTRACT.json --zip /new/company-edition.zip
```

```
uv run python -m tools.company_closeout.edition --output /new/edition --verify
```

After publication, retrieve the exact GitHub Release asset and verify its external SHA-256, internal manifest, member counts and independent import. A locally created ZIP or reserved release URL is not delivery. The indexed release receipt supplies the concrete filenames and commands for that version.

Existing portal and professional limits

Follow [PORTAL_CONTRACT.md](#). The exercised adapter imports exact originals through the existing committed CompanyStore interface in an isolated directory. It neither edits the active worktree nor reads live/private data. Reference authorization and old-snapshot restore tests have a separate scope from the CompanyStore backup. Designed, implemented, exercised, fictional operation and actual external deployment remain distinct. The existing external readiness gates are not cleared by synthetic company records or a reference software test.

The final register identifies any surviving tax, rights, engineering, artifact or runtime residual by affected claim. Ordinary fictional completion is labeled as authored; source reconstruction is not independent bank, regulator or counsel confirmation. This edition enables inspection without representing an audit opinion.

Controlled publication • Generated from docs/internal/company-closeout/INSPECTION_GUIDE.md • Do not alter PDF manually
